### 1 Model

#### 1.1 Model structure

We developed a susceptible-infective-treated coinfection model with heterogeneous mixing. Model consists of 9 states which are classified by syphilis and HIV infection status:  $SS_i$ ,  $IS_i$ ,  $TS_i$ ,  $SI_i$ ,  $II_i$ ,  $TI_i$ ,  $ST_i$ ,  $IT_i$ , and  $TT_i$ . Given a state  $XY_i$ , X represents the HIV infection status; Y represents the syphilis infection status; and i represents the risk group. For simplicity, we do not consider progression through different stages of the disease, and assume that there are only two risk groups: i=1,2.

We assume that all individuals leave at-risk population at a rate  $\mu$ , and individuals enter at-risk population as SS (susceptible to both diseas) at a constant rate that is proportional to the proportion of each risk group at a disease-free equilibrium:  $\mu N_0$ . Individuals infected syphilis receive treatment (acquiring partial immunity) at a rate  $\gamma$  and lose immunity (becoming susceptible) at a rate  $\delta$ . Individuals infected with HIV receive ARV treatment at a rate  $\tau$ . They can also leave ARV treament or treatment may fail (entering infective compartment) at a rate  $\sigma$ . Individuals infected with HIV die at a rate  $\alpha$  but if they're receiving ARV treatment, they die at a slower rate of  $\epsilon_{\alpha}\alpha$ , where  $\epsilon_{\alpha}<1$ . Individuals infected with syphilis and HIV can infect a susceptible partner at a probability of  $\beta_{syph}$  and  $\beta_{HIV}$  per partnership, respectively. ARV treatment reduces HIV transmission rate by the factor of  $\epsilon_{\beta}$ , and syphilis infection increases acuiqition and transmission rate of HIV by the factor of  $\nu_r$  and  $\nu_t$ , respectively (Deschamps et al., 1996; Røttingen et al., 2001). For simplicity, we do not consider explicit partnership dynamics but we assume assortative mixing.

## 1.2 Assortativity

Assortative mixing is modeled based on the work of Grassly et al. (2005). Proportion  $\rho$  of an individual's mixing is reserved for their own risk group, and the rest is used randomly in the whole population. Force of infection,  $\lambda_i$ , that susceptible individuals in a risk group, i, experience from a particular disease is given by the following equation:

$$\lambda_i = \rho \beta_i \frac{Y_i}{N_i} + (1 - \rho) \beta_i \frac{\sum_i c_i Y_i}{\sum_i c_i N_i},\tag{1}$$

where i is the mixing group,  $c_i$  is the partnership rate,  $N_i$  is total number of people in the mixing group, and  $\beta_i = \beta * c_i$  ( $\beta$  is the transmission probability per partnership of the disease).

#### 1.3 Transmission

In the equations introduced above,  $Y_i$  is the number of individuals in a risk group i that are infected with a particular disease. However, in order to account for varying transmissibility depending on the infection status, We define  $J_i^{HIV} = IS_i + \nu_t II_i + IT_i + \epsilon_\beta (TS_i + \nu_t TI_i + TT_i)$  and  $J_i^{syph} = SI_i + II_i + TI_i$ , which are used to calculate force of infection of two diseases:

$$\lambda_{i}^{HIV} = \rho \beta_{i}^{HIV} \frac{J_{i}^{HIV}}{N_{i}} + (1 - \rho) \beta_{i}^{HIV} \frac{\sum_{i} c_{i} J_{i}^{HIV}}{\sum_{i} c_{i} N_{i}},$$

$$\lambda_{i}^{syph} = \rho \beta_{i}^{syph} \frac{J_{i}^{syph}}{N_{i}} + (1 - \rho) \beta_{i}^{syph} \frac{\sum_{i} c_{i} J_{i}^{syph}}{\sum_{i} c_{i} N_{i}}.$$
(2)

Increased susceptibility to HIV due to syphilis is modeled by multiplying the term  $\nu_r$  to the infection term going from  $SI_i$  to  $II_i$ :  $SI_i' = -\nu_r \lambda_i^{HIV} SI_i$  and  $II_i' = -\nu_r \lambda_i^{HIV} SI_i$ .

#### 1.4 Mathematical model

$$SS'_{i} = \mu N(0)_{i} - (\lambda_{i}^{HIV} + \lambda_{i}^{syph})SS_{i} + \delta ST_{i} - \mu SS_{i}$$

$$IS'_{i} = -\lambda_{i}^{syph}IS_{i} + \lambda_{i}^{HIV}SS_{i} - \tau IS_{i} + \sigma TS_{i} + \delta IT_{i} - \alpha IS_{i} - \mu IS_{i}$$

$$TS'_{i} = -\lambda_{i}^{syph}TS_{i} + \tau IS_{i} - \sigma TS_{i} + \delta TT_{i} - \epsilon_{\alpha}\alpha TS_{i} - \mu TS_{i}$$

$$SI'_{i} = -\nu_{\tau}\lambda_{i}^{HIV}SI_{i} + \lambda_{i}^{syph}SS_{i} - \gamma SI_{i} - \mu SI_{i}$$

$$II'_{i} = \nu_{\tau}\lambda_{i}^{HIV}SI_{i} + \lambda_{i}^{syph}IS_{i} - \tau II_{i} + \sigma TI_{i} - \gamma II_{i} - \alpha II_{i} - \mu II_{i}$$

$$TI'_{i} = \lambda_{i}^{syph}TS_{i} + \tau II_{i} - \sigma_{i}TI_{i} - \gamma TI_{i} - \epsilon_{\alpha}\alpha TI_{i} - \mu TI_{i}$$

$$ST'_{i} = -\lambda_{i}^{HIV}ST_{i} + \gamma SI_{i} - \delta ST_{i} - \mu ST_{i}$$

$$IT'_{i} = \lambda_{i}^{HIV}ST_{i} - \tau IT_{i} + \sigma TT_{i} + \gamma II_{i} - \delta IT_{i} - \alpha IT_{i} - \mu IT_{i}$$

$$TT'_{i} = \tau IT_{i} - \sigma TT_{i} + \gamma TI_{i} - \delta TT_{i} - \epsilon_{\alpha}\alpha TT_{i} - \mu TT_{i}$$

## 1.5 Delayed introduction of ARV

Instead of using the model as it is above, we introduce ARV treatment 20 years after the beginning of the simulation. It is simply done by multiplying  $T_{start}$  to  $\tau$  ( $\tau_{adj} = T_s tart \tau$ ) and setting  $T_{start} = 0$  when t < 20 and 1 otherwise. With the introduction of ARV, we introduce two more variables to the model:  $\nu_{IS}$ 

and  $c_{inc}$ .  $\nu_{IS}$  is the ratio of increased susceptibility to syphilis due to ARV immunosuppression effect and  $c_{inc}$  is the effect of ARV on behaviour (also given as a ratio).  $\nu_{IS}$  is simply multiplied to syphilis infection term going from  $TS_i$  to  $TI_i$ .  $TS_i' = -\nu_{IS} \lambda_i^{syph} TS_i$  and  $TI_i' = \nu_{IS} \lambda_i^{syph} TS_i$ .

With the introdction of ARV, behaviour change is introduced to people who are receiving ARV. The behaviour change is modeled by multiplying  $c_{inc}$  to the partnership change rate of those who are receiving ARV. It is done by modifying J, N, as well as the infection term going from  $TS_i$  ti  $TI_i$ :

$$\begin{split} J_{i}^{HIV} &= IS_{i} + \nu_{t}II_{i} + IT_{i} + c_{inc}\epsilon_{\beta}(TS_{i} + \nu_{t}TI_{i} + TT_{i}), \\ J_{i}^{syph} &= SI_{i} + II_{i} + c_{inc}TI_{i}, \\ N_{i} &= SS_{i} + IS_{i} + SI_{i} + II_{i} + ST_{i} + TT_{i} + c_{inc}(TS_{i} + TI_{i} + TT_{i}) \\ TS'_{i} &= -c_{inc}\nu_{IS}\lambda_{i}^{syph}TS_{i} \\ TI'_{i} &= c_{inc}\nu_{IS}\lambda_{i}^{syph}TS_{i}. \end{split} \tag{4}$$

Increase in behaviour change is modeled by using the exponential function:  $c_{inc} = c_f + (c_0 - c_f) exp((T_{start} - t)/T_c)$ . These equations replace the equations in the above model.
